DOUGLAS SQUIRREL (*Tamiasciurus douglasii*)

HABITAT USE INFORMATION

General

The Douglas' squirrel (*Tamiasciurus douglasii*) inhabits coniferous, mixed-coniferous, and subalpine forests from southwestern British Columbia through the western half of Washington, and the western two-thirds of Oregon and northern California (Hall 1981). In California, they are common yearlong residents of conifer, hardwood-conifer, and riparian habitats from sea level to 3,333 m (11,000 ft) in the North Coast, Cascade, Klamath, Warner, and Sierra Nevada Ranges (Zeiner et al. 1990). Douglas' squirrels are diurnal and are active throughout the year (Maser 1981).

Food

Though Douglas' squirrels subsist largely on conifer seeds and fungi, they also consume pollen cones and cambium of conifers, mast, twigs, sap, leaves, buds, and occasionally arthropods, birds eggs, nestlings, and carrion (Ingles 1965; Smith 1970, 1981; Zeiner et al. 1990). Douglas' squirrels forage both in trees and on the ground, and cache food for winter use. Food caches of Douglas' squirrels seem to be smaller than those of red squirrels (*T. hudsonicus*) and appear large enough to last only six to nine months (Koford 1982; Carey 1991). In the Sierra Nevada, caches of 1,800 to 2,500 cones were found in springs and seeps, but caches were more commonly found with caches containing an average of six cones (range one to 20) beneath logs (Shaw 1936). In Oregon, caches averaging 200 cones were found along streams, in moist depressions, in or under logs, and on the ground beneath moss (Lavender and Engstrom 1956). Douglas' squirrels are adept at finding hypogeous fungi and may consume as many as 89 different species (Fogel and Trappe 1978). Fungi may also be cached (Lindsay 1986).

Water

No specific requirements have been reported in the literature. It is likely that they meet water needs from the food they consume (Zeiner et al. 1990).

Cover

Douglas' squirrels require a forest mosaic that includes adequate denning and feeding areas. They utilize a variety of shelters including tree cavities, hollow trees and logs, and ground burrows (Maser 1981; Smith 1968). Loosely constructed stick nests are commonly used during summer, while weather-tight nests in dense foliage, hollow trees, or cavities are used during winter. During a prolonged, severe winter, underground nests in the main food midden may be used (Carey 1991).

In the Pacific northwest, Douglas' squirrels are found in open and closed sapling-pole, large sawtimber, and old-growth stands in coniferous, mixed-coniferous, and subalpine forests. Secondary habitats include hardwood and shrubby wetlands, coniferous wetlands, lodgepole pine (*Pinus contorta* var. *murrayana*), shorepine (*P. c.* var. *contorta*), and conifer-hardwood forests (Brown 1985). In northern California, a positive correlation has been found between stand age (55-315 yr) and Douglas' squirrel abundance (Raphael 1984; Ralph et al. 1991). However, in southwestern Oregon and in the Oregon and Washington Cascades, differences in spring squirrel abundance were not found among closed sapling-pole-small sawtimber and old-growth Douglas-fir stands (*Pseudotsuga menziesii*) (Carey 1989). Buchanan et al. (1990) found that during winter in the Washington Cascades, Douglas' squirrels were more abundant in old-growth stands than in closed sapling-pole-small sawtimber and large saw-log stands. Maximum seed production in Douglas-fir occurs when the trees are between 200 and 300 years of age (Fowells 1965), and thus after the stand has attained some old-growth characteristics (Franklin et al. 1981). Because squirrel populations are limited during winter by the availability of conifer seeds (Smith 1968, 1970), larger squirrel populations in old-growth stands probably occur because food resources are larger and more reliable. Immigration to areas of high food abundance has been reported by Sullivan and Sullivan (1982). Old-growth stands may also provide better overwintering habitat (Carey 1991).

Reproduction

Douglas' squirrels generally breed once per year, occasionally twice, depending upon the date of birth of the female and the size of the cone crop. Litters are typically born May to June (Smith 1965, 1968; Koford 1982; Zeiner et al. 1990). The reproductive requirements of the Douglas' squirrel are assumed to be met by the cover types described above.

Interspersion and Composition

Male and female Douglas' squirrels defend individual territories, but the defense is generally relaxed only during the breeding season. Territorial defense also may be relaxed in the spring when male conifer cones are abundant, and territories may be abandoned during food shortages (Carey 1991). Home range and territory coincide (Smith 1968). Territories are small (0.2-1.2 ha [0.5-3 ac]) and average 128 m (425 ft) in diameter (Carey 1991). Good habitat may support squirrel densities of 2/ha (2.5 ac) (Zeiner et al. 1990). In western Washington, squirrel densities varied from 0.1-1.4/ha (2.5 ac) in old-growth Douglas-fir stands and from 0.03-0.8/ha (2.5 ac) in young (42-140 yr) stands (Buchanan et al. 1990).

HABITAT SUITABILITY INDEX (HSI) MODEL

Model Applicability

Geographic area.

The California Wildlife Habitat Relationships (CWHR) System (Airola 1988; Mayer and Laudenslayer 1988; Zeiner et al. 1990) contains habitat ratings for each habitat type predicted to be occupied by Douglas' squirrel in California.

Season.

This model is designed to predict the suitability of habitat for Douglas' squirrels throughout the year. Model predictions, however, may be more accurate for breeding habitat.

Cover types.

This model can be used anywhere in California for which an ARC/INFO map of CWHR habitat types exists. The CWHR System contains suitability ratings for reproduction, cover, and feeding for all habitats Douglas' squirrels are predicted to occupy. These ratings can be used in conjunction with the ARC/INFO habitat map to model wildlife habitat suitability.

Minimum habitat area.

Minimum habitat area is defined as the minimum amount of contiguous habitat required before a species will occupy an area. Specific information on minimum areas required for Douglas' squirrel was not found in the literature. This model assumes two home ranges is the minimum area required to support a Douglas' squirrel population during the breeding season.

Verification level.

The spatial model presented here has not been verified in the field. The CWHR suitability values used are based on a combination of literature searches and expert opinion. We strongly encourage field testing of both the CWHR database and this spatial model.

Model Description

Overview.

This model uses CWHR habitat type as the main factor determining suitability of an area for this species.

A CWHR habitat type map must be constructed in ARC/INFO GRID format as a basis for the model. The GRID module of ARC/INFO was used because of its superior functionality for spatial modeling. Only crude spatial modeling is possible in the vector portion of the ARC/INFO program, and much of the modeling done here would have been impossible without the abilities of the GRID module. In addition to more sophisticated modeling, the GRID module's execution speed is very rapid, allowing a complex model to run in less than 30 minutes.

The following sections document the logic and assumptions used to interpret habitat suitability.

Cover component.

A CWHR habitat map must be constructed. The mapped data (coverage) must be in ARC/INFO GRID format. A grid is a GIS coverage composed of a matrix of information. When the grid coverage is created, the size of the grid cell should be determined based on the resolution of the habitat data and the home range size of the species with the smallest home range in the study. You must be able to map the home range of the smallest species with reasonable accuracy. However, if the cell size becomes too small, data processing time can increase considerably. We recommend a grid cell size of 30 m (98 ft). Each grid cell can be assigned attributes. The initial map must have an attribute identifying the CWHR habitat type of each grid cell. A CWHR suitability value is assigned to each grid cell in the coverage based on the habitat type. Each CWHR habitat is rated as high, medium, low or of no value for each of three life requisites: reproduction; feeding; and cover. The geometric mean value of the three suitability values was used to determine the base value of each cell for this analysis.

Distance to water.

No water requirement was found for this species.

Species' distribution.

The study area must be manually compared to the range maps in the CWHR Species Notes (Zeiner et al. 1990) to ensure that it is within the species' range. All grid cells outside the species' range have a suitability of zero.

Spatial analysis.

Ideally a spatial model of distribution should operate on coverages containing habitat element information of primary importance to a species. For example, in the case of woodpeckers, the

size and density of snags as well as the vegetation type would be of great importance. For many small rodents, the amount and size of dead and down woody material would be important. Unfortunately, the large cost involved in collecting microhabitat (habitat element) information and keeping it current makes it likely that geographic information system (GIS) coverages showing such information will be unavailable for extensive areas into the foreseeable future.

The model described here makes use of readily available information such as CWHR habitat type, elevation, slope, aspect, roads, rivers, streams and lakes. The goal of the model is to eliminate areas that are unlikely to be utilized by the species and lessen the value of marginally suitable areas. It does not attempt to address all the microhabitat issues discussed above, nor does it account for other environmental factors such as toxins, competitors, or predators. If and when such information becomes available, this model could be modified to make use of it.

In conclusion, field surveys will likely discover that the species is not as widespread or abundant as predictions by this model suggest. The model predicts potentially available habitat. There are a variety of reasons why the habitat may not be utilized.

Definitions.

Home Range: the area regularly used for all life activities by an individual during the season(s) for which this model is applicable.

Dispersal Distance: the distance an individual will disperse to establish a new home range. In this model it is used to determine if Potential Colony Habitat will be utilized.

Day to Day Distance: the distance an individual is willing to travel on a daily or semi-daily basis to utilize a distant resource (Potential Day to Day Habitat). The distance used in the model is the home range radius. This is determined by calculating the radius of a circle with an area of one home range.

Core Habitat: a contiguous area of habitat of medium or high quality that has an area greater than two home ranges in size. This habitat is in continuous use by the species. The species is successful enough in this habitat to produce offspring that may disperse from this area to the Colony Habitat and Other Habitat.

Potential Colony Habitat: a contiguous area of habitat of medium or high quality that has an area between one and two home ranges in size. It is not necessarily used continuously by the species. Distance from a core area will affect how often it is used.

Colony Habitat: Potential Colony Habitat that is within the dispersal distance of the species. These areas receive their full original value unless they are further than three home range radii

from a core area. These distant areas receive a value of low since there is a low probability that they will be utilized regularly.

Potential Day to Day Habitat: an area of high or medium quality habitat less than one home range, or habitat of low quality of any size. This piece of habitat alone is too small or of inadequate quality to be Core Habitat.

Day to Day Habitat: Potential Day to Day Habitat that is close enough to Core or Colony Habitat can be utilized by individuals moving out from those areas on a day to day basis. The grid cell must be within Day to Day Distance of Core or Colony Habitat.

Other Habitat: contiguous areas of low value habitat larger than two home ranges in size, including small areas of high and medium quality habitat that may be imbedded in them, are included as usable habitat by the species. Such areas may act as “sinks” because long-term reproduction may not match mortality.

The table below indicates the specific distances and areas assumed by this model.

Distance variables:	Meters	Feet
Dispersal Distance	4,500	14,765
Day to Day Distance/ Home Range radius	72	236

Area variables:	Hectares	M ²	Acres	Ft ²
Home Range	1.62	16,188	4	174,240
Core Habitat	3.24	32,376	8	348,480

Application of the Model

A copy of the ARC/INFO AML can be found in Appendix 1. The steps carried out by the macro are as follows:

1. **Determine Core Habitat:** this is done by first converting all medium quality habitat to high quality habitat and removing all low value habitat. Then contiguous areas of habitat are grouped into regions. The area of each of the regions is determined. Those large enough (two home ranges) are maintained in the Core Habitat coverage. If no Core Habitat is identified then the model will indicate no suitable habitat in the study area.

2. **Identify Potential Colony Habitat:** using the coverage from Step 1, determine which regions are one to two home ranges in size. These are Potential Colonies.
3. **Identify Potential Day Use Habitat:** using the coverage derived in Step 1, determine which areas qualify as Potential Day to Day Habitat.
4. **Calculate the Cost Grid:** since it is presumed to be more difficult for animals to travel through unsuitable habitat than suitable habitat we use a cost grid to limit travel based on habitat suitability. The cost to travel is one for high or medium quality habitat. This means that to travel 1 m through this habitat costs 1 m of Dispersal Distance. The cost to travel through low quality habitat is two and unsuitable habitat costs four. This means that to travel 1 m through unsuitable habitat costs the species 4 m of Dispersal Distance.
5. **Calculate the Cost Distance Grid:** a cost distance grid containing the minimum cost to travel from each grid cell to the closest Core Habitat is then calculated using the Cost Grid (Step 4) and the Core Habitat (Step 1).
6. **Identify Colony Habitat:** based on the Cost Distance Grid (Step 5), only Potential Colony Habitat within the Dispersal Distance of the species to Core Habitat is retained. Colonies are close enough if any cell in the Colony is within the Dispersal Distance from Core Habitat. The suitability of any Colony located further than three home range radii from a Core Habitat is changed to low since it is unlikely it will be utilized regularly.
7. **Create the Core + Colony Grid:** combine the Core Habitat (Step 1) and the Colony Habitat (Step 6) and calculate the cost to travel from any cell to Core or Colony Habitat. This is used to determine which Potential Day to Day Habitat could be utilized.
8. **Identify Day to Day Habitat:** grid cells of Day to Day Habitat are only accessible to the species if they are within Day to Day Distance from the edge of the nearest Core or Colony Habitat. Add these areas to the Core + Colony Grid (Step 7).
9. **Add Other Habitat:** large areas (two home ranges in size) of low value habitat, possibly with small areas of high and medium habitat imbedded in them may be utilized, although marginally. Add these areas back into the Core + Colony + Day to Day Grid (Step 8), if any exist, to create the grid showing areas that will potentially be utilized by the species. Each grid cell contains a one if it is utilized and a zero if it is not.
10. **Restore Values:** all areas that have been retained as having positive habitat value receive their original geometric mean value from the original geometric value grid (see

Cover component section) with the exception of distant colonies. Distant colonies (colonies more than three home range radii distant) have their value reduced to low because of the low likelihood of utilization.

Problems with the Approach

Cost.

The cost to travel across low suitability and unsuitable habitat is not known. It is likely that it is quite different for different species. This model incorporates a reasonable guess for the cost of movement. A small bird will cross unsuitable habitat much more easily than a small mammal. To some extent differences in vagility between species is accounted for by different estimates of dispersal distances.

Dispersal distance.

The distance animals are willing to disperse from their nest or den site is not well understood. We have used distances from studies of the species or similar species when possible, otherwise first approximations are used. More research is urgently needed on wildlife dispersal.

Day to day distance.

The distance animals are willing to travel on a day to day basis to use distant resources has not been quantified for most species. This issue is less of a concern than dispersal distance since the possible distances are much more limited, especially with small mammals, reptiles, and amphibians. Home range size is assumed to be correlated with this coefficient.

SOURCES OF OTHER MODELS

No other habitat models were found for the Douglas' squirrel.
